## Disclosures

- **KT** has received research grant support and consultancy fees from Travers Therapeutics, Inc.
- **CA** and **PW** received consultancy fees from Travers Therapeutics, Inc.
- **MB** is a consultant for Travers Therapeutics, Inc.
- **KW** is an employee and stockholder of Travers Therapeutics, Inc.
- **JH** and **AR** are employees of Genesis Research which received compensation from Travers Therapeutics, Inc. for conducting this study

## Acknowledgements

- The biopsy studies were conducted in the Arkana Laboratories.
- This study was funded by Travers Therapeutics, Inc.
- Writing support was provided by David Cork and Eve Hunter-Featherstone (Genesis Research).

- Focal segmental glomerulosclerosis (FSGS) is a lesion of glomerular injury in patients with nephrotic syndrome
- FSGS often follows a progressive course to kidney failure (KF), and FSGS is a leading glomerular cause of KF in the US<sup>1-3</sup>
- Persistent podocyte injury leads to proteinuria and a progressive decline in eGFR<sup>3-6</sup>

## Objectives

- To assess histopathological characteristics of FSGS at diagnosis
- To assess clinical predictors of the histological severity of FSGS among adults undergoing kidney biopsy

**Abbreviations:** **FSGS**, focal segmental glomerulosclerosis; **KF**, kidney failure; **eGFR**, estimated glomerular filtration rate

## Study design, data source and inclusion criteria

- This is a study of real-world data collected from patients with biopsy-confirmed FSGS in the US from the Arkana Biopsy database from January 1, 2016 to May 31, 2020
- Included patients: (1) were  $\geq 18$  years of age, (2) had at least 1 FSGS-positive kidney biopsy during the study period (January 1, 2016 – May 31, 2020), (3) had no prior kidney transplant

## Measures and statistical analyses

- Histological characteristics were assessed in the overall cohort and stratified by race as White vs. Non-White (Black, Asian, other, unknown). Chi-squared tests were used to compare categorical variables between race groups
- Severe histological disease was defined by a composite measure combining GS in  $\geq 50\%$  of glomeruli and IFTA in  $\geq 25\%$  the tubulointerstitium
- Categorical variables were summarized using frequencies and percentages. Continuous variables were summarized using means, SD, medians, and interquartile ranges
- A multiple logistic regression model was used to assess the associations of CKD stage and proteinuria with severe histological disease, adjusting for age, sex, race, and hypertension

## Arkana Laboratories

- Arkana Laboratories provides renal pathology, serology, molecular pathology, and neuropathology services from healthcare institutions across 40 states in the US. Patient clinical characteristics are retrospectively collected at time of biopsy

## Histology

- Kidney biopsy examination techniques were used, including light and electron microscopy<sup>7</sup>
- Light microscopy samples were fixed in formalin; embedded in paraffin and serially cut at 3  $\mu\text{m}$ ; and stained with hematoxylin & eosin, Jones methenamine silver, Masson trichrome, or periodic acid–Schiff reagent
- For electron microscopy, 1 mm cubes were removed from the ends of the biopsy sample, dehydrated with graded alcohols and embedded in Epon/Araldite resin. Sections of 1  $\mu\text{m}$  were cut with an ultramicrotome and stained with toluidine blue and examined with a light microscope for glomerular evaluation. Thin sections were cut at 60 nm and examined in a Jeol JEM 1011 electron microscope (Jeol, Tokyo, Japan) and photomicrographs were taken at 4,000, 12,000 and 20,000 x magnification

## Demographic and clinical characteristics

- The cohort consisted of 2,011 adult patients (age  $\geq 18$  years). Mean age was 49.1 years, 43.6% were female
- 40.6% were White. Race information was not available for 26.3% of the cohort
- Proteinuria data were available for 65.9% of patients. Median urinary protein-creatinine ratio (UP/C) was 3.8 g/g, median 24-hour urinary protein was 4.7 g/day
- Nephrotic range proteinuria was observed in 62.1% of patients with available proteinuria data
- Median eGFR was 42.2 mL/min/1.73 m<sup>2</sup> and among patients with available eGFR (83.7%), the majority were CKD stages 3–5 at diagnosis (68.0%)

Table 1. Demographic and clinical characteristics

	N=2,011
<b>Age, Mean (SD), years</b>	49.1 (17.2)
<b>Gender, n (%), Female</b>	877 (43.6)
<b>Race, n (%)</b>	
White	817 (40.6)
Non-White	1,194 (59.4)
Black	417 (23.6)
Hispanic	114 (5.7)
Asian	51 (2.5)
Other	26 (1.3)
Unknown	529 (26.3)
<b>Proteinuria data available, n (%)</b>	1,326 (65.9)
<b>UP/C available, n (%)</b>	557 (42.0)
Median (Q1,Q3), g/g	3.8 (2.0,7.0)
<b>24-hour urinary protein available, n (%)</b>	769 (58.0)
Median (Q1,Q3), g/day	4.7 (3.0,9.0)
<b>Nephrotic range proteinuria,* n (%)</b>	824 (62.1) <sup>†</sup>
<b>eGFR, ‡ median (Q1,Q3), mL/min/1.73 m<sup>2</sup></b>	42.2 (25.3,72.0)
CKD stage available, n (%)	1,684 (83.7)
Stage 1	257 (15.3)
Stage 2	282 (17.8)
Stage 3	599 (35.6)
Stage 4	383 (22.7)
Stage 5	163 (9.7)

\*Defined as proteinuria  $\geq 3$  g/g or  $\geq 3.5$  g/day; <sup>†</sup>Percentage of patients with available proteinuria data; <sup>‡</sup>Based on CKD-EPI 2021 equation

## Histopathological features of FSGS at diagnosis

- Global GS of  $\geq 50\%$  of glomeruli was observed in the biopsies of 21.8% of patients
- IFTA  $\geq 50\%$  in the tubulointerstitial compartment was present in 21.8% of patients
- Diffuse foot process effacement (FPE) ( $\geq 80\%$  of glomeruli) was seen in almost half of patients
- More than two thirds of patients had FSGS with NOS (not otherwise specified) type lesions

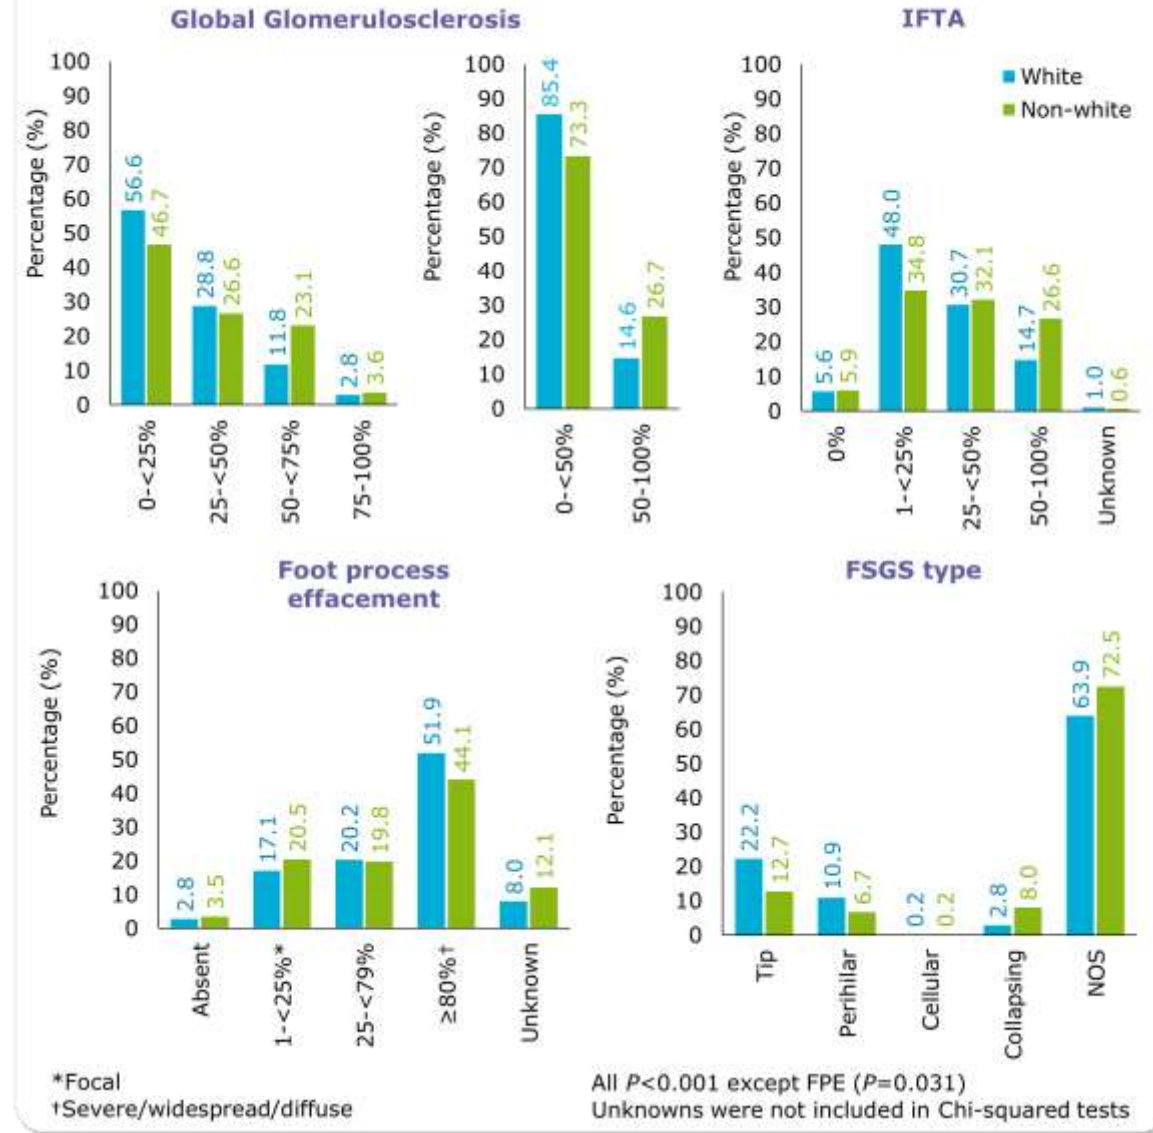

Figure 1. Histopathological characteristics at diagnosis (overall)

## Histopathological features of FSGS at diagnosis by race/ethnicity

- Significant differences in histopathological characteristics and FSGS subtypes were observed between White and Non-White groups
- GS  $\geq 50\%$  and IFTA  $\geq 50\%$  were observed more frequently in the Non-White group compared with the White group while severe FPE was observed more frequently in the White group
- NOS and collapsing lesions both occurred in a significantly higher proportion of patients in the Non-White group

Figure 2. Histopathological characteristics at diagnosis (by race)

## Clinical predictors of histological disease severity

- CKD stages 3-5 were associated with significantly higher odds of severe histological disease than stages 1-2
- Non-White race and hypertension were also associated with severe histological disease
- Older age was associated with significantly lower odds of severe histological disease
- Neither nephrotic-range proteinuria nor sex were significantly associated with histological disease severity

Figure 3. Clinical predictors of histologically severe FSGS

Reference groups: <sup>a</sup>CKD stages 1 and 2; <sup>b</sup>Non-nephrotic proteinuria; <sup>c</sup>18 - 44 years; <sup>d</sup>Female; <sup>e</sup>White; <sup>f</sup>No

- Most patients (68%) had CKD stage  $\geq 3$  and over a fifth (23%) had  $\geq 50\%$  GS or IFTA. Non-White race was associated with a significantly higher frequency of advanced GS or IFTA
- $\sim 70\%$  of patients had NOS lesions. Non-White race was associated with a higher frequency of NOS or collapsing lesions and fewer tip or perihilar lesions
- The risk of severe histological disease was significantly greater with later CKD stages. Nephrotic-range proteinuria was not significantly associated with severe histological disease, but further analysis may show association with more severe FPE
- Younger age, Non-White race, and hypertension were associated with increased risk of severe histological disease

## Limitations

- Generalizability may be limited by unequal distribution of patients across the 40 states serviced by Arkana within the database. Reasons for missing demographic/clinical data could not be assessed. The number of patients in Non-White race/ethnicity groups was small. Unknown race was included in the Non-White group which could have led to undetected bias

## Conclusions

- Severe histologic features of FSGS are predicted by later CKD stage, but not nephrotic range proteinuria, at the time of kidney biopsy
- Younger, Non-White, and hypertensive patients are at greater risk of severe histologic FSGS
- Strategies for earlier diagnosis before onset of eGFR decline and severe structural injury are needed, especially in high-risk groups, to improve kidney disease outcomes in patients with FSGS
